Treat first data releases with caution, says lecturer

October 20, 2006

By Ethel Hazelhurst

Johannesburg - The release of important economic data always makes headlines. But Corne van Walbeek, a senior lecturer at the University of Cape Town (UCT), warned yesterday that the statistical authorities and the financial press should treat initial releases with caution.

Van Walbeek, of UCT's school of economics, raised the issue in a paper presented at a conference arranged by the Development Policy Research Unit. He said first data releases and final releases "can differ quite substantially".

The discrepancy has important implications for policy making because economic information influences the decisions of Reserve Bank on interest rates, finance

minister Trevor Manuel's budget decisions and the private sector's investment decisions.

The consequences of publishing incorrect information were illustrated in 2001 and 2002 when faulty methodology for determining rental prices distorted the outcome of CPIX (the consumer price index excluding mortgages). CPIX was overstated for a period and led to a series of unnecessary interest rate rises in 2002 and 2003, which, in turn, led to a slowing in growth.

Statistics SA is under great pressure to provide policy makers and the public with accurate and timely information. But Van Walbeek pointed out there was always a trade-off between accuracy and timeliness and decisions could not wait until final data were available. And the reality was that the best data available when decisions were made were "provisional and uncertain and could be substantially revised".

In South Africa, the first estimates of gross domestic product (GDP) were released by Stats SA "about 60 days after the end of the relevant quarter", said Van Walbeek. They were "calculated according to the production approach", which meant they were a measure of volumes produced.

The Reserve Bank makes an independent calculation, based on data from the SA Revenue Service, government departments and surveys of economic activity. This process measures GDP in terms of expenditure and the results are published in the central bank's Quarterly Bulletin, a few weeks after the initial release from Stats SA.

"From a policy and publicity perspective, it is these first releases that attract the most attention," said Van Walbeek.

The variations between initial and final data have implications for policy makers and economic analysts who base projections on the latest available data.

Van Walbeek discussed important macroeconomic relationships, including that between household consumption and imports. Strong household spending boosts import growth and strong import growth tends to produce a current account deficit - a shortfall between revenue earned from exports of goods and services and the cost of imports - unless export growth is very strong.

So the Reserve Bank traditionally raises interest rates to cut borrowing and spending, when there is a need to reduce imports.

For this reason, the extent to which growth in household consumption fuels growth in imports is critical in South Africa's environment, when the deficit is running at 6.1 percent of GDP, well above acceptable levels. It was one of the major factors that influenced the Reserve Bank's monetary policy committee (MPC) to raise the repo rate by 1.5 percentage points since June. And it will remain a major factor when the MPC meets in December.

Van Walbeek pointed out the data revisions were not out of line with those in members countries of the Organisation of Economic Co-operation and Development. The problem has no obvious solution. Van Walbeek said his paper probably "raises more questions than answers".
